HANGER BAR ASSEMBLY

FIELD OF INVENTION:

The present invention relates generally to a hanger bar assembly for supporting electrical fixtures. More particularly, the present invention relates to a hanger bar assembly having channel members that are slidably engagable, wherein longitudinal relative motion of the channel members is restricted upon securement of an electrical outlet box to the channel members.

BACKGROUND OF THE INVENTION:

In order to secure electrical fixtures such as lights and fans in ceilings, a hanger bar device is typically employed. It is very important that a fixture be adequately supported in the ceiling since improper support could lead to the fixture breaking away from the ceiling. Ceilings are typically constructed of structural members including a series of spaced joists which are covered by lathe and plaster or a gypsum wallboard often referred to as drywall. The ceiling covering material or sheathing is not designed to support loads perpendicular to its surfaces. Therefore, in order to suspend electrical fixtures from a ceiling, the fixture's weight must be supported by the joists. To achieve this, a fixture may be secured directly to a joist, however, this limits the range of locations where the fixture may be placed. Such a limitation is problematic since it is often desirable to place the fixture in a specific position on the ceiling. Therefore, if no joist is adjacently positioned to the desired location, direct joist connection is not possible. A preferred solution for supporting electrical fixtures in the ceiling is the use of a hanger bar assembly. The hanger bar allows for the joists to be used for supporting an electrical fixture while still providing flexibility in positioning.

Hanger bar assemblies are typically extensible members that are disposed in between the ceiling joists and are securable thereto. An assembly's length, therefore, is adjustable to accommodate various joist spacing distances. Electrical outlet boxes, junction boxes and the like are then secured to the transverse members of the assembly. Such electrical boxes provide a termination point for electrical wiring as well as an attachment point for the electrical fixture. Typically the outlet box can be positioned at various points along the length

of the members in order to properly position the fixture attached thereto. In conventional construction a cut out is made in the ceiling covering material in order to provide clearance for the electrical outlet box, thereby allowing the fixture to be secured to the outlet box.

The outlet box once secured to the hanger bar assembly is typically used to support the electrical fixture. The National Electric Code sets a maximum weight that an outlet box may support. Outlet boxes may either support lighting fixtures weighing up to 50 lbs. or ceiling fans weighing up to 35 lbs. Fixtures exceeding these weight limits must be supported independently of the box such as directly to the joists or other structural member.

Hanger bar assemblies can be divided into two general categories, standard and heavy duty and are distinguishable by the amount of weight they can safely support. Standard hanger bars are typically used to support lightweight lighting fixtures that are generally less than five pounds.

U.S. Patent No. 2,925,236 to Cook et al. discloses a standard duty hanger bar assembly. The assembly includes telescopically engagable slotted channel members positionable between two ceiling joists. A box carrier is inserted in the channel members and has guide prongs extending from the slots. An outlet box is insertable over the prongs and is secured to the assembly by a box fastener which is securable to the box carrier by a threaded bolt. Upon the tightening of the bolt, a portion of the outlet box and a portion of the channel members are clamped together between the box carrier and fastener, thereby securing the box to the assembly. The box carrier, however, only engages a small amount of channel section thereby providing a relatively small clamping area. Accordingly, this assembly is suited for light duty applications such as small to medium sized light fixtures, which present static loadings.

Heavy duty hanger bars are typically employed for supporting heavy lighting fixtures up to 50 lbs. and ceiling fans weighing 35 lbs. Ceiling fans require high load bearing supports not only due to their weight but also due to the torque and vibrational forces that are generate by the rotation of the motor and fan blades. Relatively small weight differences

from the center of the plate and is used to secure the box to the plate. The flanges of both channels extend downwardly at a slight angle. When the outlet box is secured to the channel members the flanges are forced together thereby clamping the two channel members together. The flanges, however, are relatively short thereby creating only a small amount of contact area between the flanges. Such limited amount of contact or clamping area limits the assembly's ability to resist slippage.

The Reiker Heavy Duty Slide Support System further includes a pair of end plates extending from the opposed ends of the assembly. The end plates are formed from upwardly bent extensions of the top wall of the channels. The end plates, therefore, are connected to the channels by a relatively thin strip of material. This design limits the assembly's ability to resist vibrational forces acting perpendicular to the channels. Such forces tend to cause the channel members to flex about the connection strip. This problem is exasperated by locating the connection strip above the assembly is neutral axis passing through the longitudinal centroid of the channel members. The offset between the connection strip and the neural axis creates a moment about the thin strip of connecting material and further reduces the assembly's ability to resist vibrational forces.

U.S. Patent No. 5,934,631 to Becker et al. further discloses a telescoping hanger bar assembly that is capable of supporting relatively heavy loads such as ceiling fans. The channel members each have a different profile to allow one to slide freely within the other. A plate is supported within the channel members and is attachable to an outlet box, which is rated to support ceiling fans. One such outlet box is described in U.S. Patent No. 5,824,952. Attachment of the box to the plate results in a clamping force which urges overlying flanges of the channel members into engagement.

The telescoping members of the prior art hanger bars are typically channels formed having different cross-section so that one member is received in the other member. In order to achieve rigidity between the members, it is important to obtain a close fit between the two members. However, the fit must permit the members to freely slide so the length of the hanger bar can be easily adjusted to accommodate securement between the joists. This is

very difficult to consistently achieve especially when the members are extruded. Extruded profiles will vary from run to run based on the thermal expansion of the die. Since the channel members must always slidingly fit together, the members are necessary toleranced to permit a certain amount of play between the members. This play between members, however, reduced the rigidity of the assembly and limits its load bearing and vibration resistance capability.

Accordingly, it would be desirable to devise a hanger bar assembly capable of supporting heavy loads such as ceiling fans that can be quickly installed and relatively simple to produce as well as being sufficiently rigid to resist vibrational forces under the heavy load of a fixture.

SUMMARY OF THE INVENTION:

It is an advantage of the present invention to provide a hanger bar assembly for rigidly supporting an outlet box between spaced apart support elements.

It is a further advantage of the present invention to provide a hanger bar assembly including a pair of interlocking engageable channel members which may be adjusted to an operating length and clamped to prevent relative channel member movement.

It is still a further advantage of the present invention to provide a hanger bar assembly including a joist engaging device which provides an installer with positive notice of proper engagement.

In the efficient attainment of these and other objects the present invention provides a hanger bar assembly for supporting an outlet box between spaced apart support elements including a first channel member being longitudinally slidingly engagable with a second channel member forming a longitudinally adjustable support bar. A first channel member includes a plurality of longitudinally extending first grooves and a plurality of longitudinally extending first rails is provided. The second channel member includes a plurality of

longitudinally extending second rails and a plurality of longitudinally extending second grooves. The first rails are slidably received in said second grooves and the second rails being slidably received in the first grooves such that lateral movement between the first and second channel members is resisted. A clamping device for urging the flanges into force engagement with the transverse extent of a corresponding channel member is also provided, thereby restricting movement between the first and second channel members. Additionally, a securement device is provided for securing the support bar to the spaced support elements.

In a preferred embodiment the first and second channel members include apertures formed therein to receive fastening hardware to secure said end plates to the support. Both channel members may include a plurality of cooperating grooves and rails formed therein which provide rigidity to the hanger bar assembly. The channel members preferably have substantially the same cross-sectional profile. In the preferred embodiment, the channel members may be extruded with the various features including the apertures, grooves and rails formed during the extrusion process.

The present invention also provides a hanger bar assembly for supporting an outlet box between spaced apart support elements including a first channel member being longitudinally slidably engagable with a second channel member forming an longitudinally adjustable support bar. The first and second channel members upon mutual engagement form a plurality of laterally spaced interlocking rail and groove combinations to resist lateral and rotational movement between the first and second channel members. The assembly further includes a clamping device for urging the first and second channel members into respective forced engagement thereby restricting movement between the first and second channel members. A securement device attached to the support bar is provided for securing the support bar to the spaced support elements.

The present invention also provides a hanger bar assembly for supporting an outlet box between spaced apart support elements including a first channel member being longitudinally slidably engagable with a second channel member. Each of the first and second channel members include a pair of side walls spaced by a connecting wall to form a

channel interior. The first channel members has a plurality of longitudinally extending shims projecting therefrom and being engagable with opposed surfaces of the second channel member. The shims effect a fit between the first and second channel members. A clamp for urging the first and second channel members into respective forced engagement thereby restricting movement between the first and second channel members. A securement device attached to the first and second channel members for securing the hanger bar assembly to the spaced support elements is further provided.

A preferred form of the hanger bar assembly, as well as other embodiments, advantages, and features of this invention will be apparent from the following detailed description of illustrative embodiments thereof, which is to be read in connection with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS:

Figure 1 is a perspective view of the hanger bar assembly of the present invention with an outlet box secured thereto.

Figure 2 is an exploded perspective view of the hanger bar assembly of Figure 1.

Figure 3 is an elevational end view of a channel member of the present invention.

Figure 4 is a cross-sectional view of the assembly taken along line III-III of Figure 1.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT:

The hanger bar assembly of the present invention is adapted to support relatively heavy electrical fixtures such as ceiling fans in "new work" applications where the ceiling covering material such as plaster or drywall has yet to be installed and where the joists are substantially exposed. Ceiling fans, in addition to being relatively heavy, typically create cyclic loadings and vibrational forces due to the rotation of the motor and fan blades. Such forces must be adequately supported in order to ensure the fixture does not separate from the ceiling support structures to which it is attached. The hanger bar assembly of the present invention provides support for such fixtures as ceiling fans by maintaining its rigidity in configuration even under relatively high loadings.

In order to further ensure a play-free engagement between first and second channel members, 20 and 22, the present invention further includes longitudinally extending shims 37 protruding from second side wall 25. Shims 37 preferably include relatively thin, ridge-like projections that engage opposing surfaces when the two channel members are assembled. If the fit is too tight and the channel members are difficult to assembly or slide, shims 37 may be easily abraded off. This is especially true when the channel material is aluminum due the materials ease of workability.

The use of shims 37 also permits for tooling used to form channel members 20 and 22 to be economically produced. For extruded material dies are produced that give shape to the channel members. These dies have a significant cost associated with their development. If the material extruded through the dies does not permit the proper clearance resulting in either too much play or too much sliding resistances, either new dies would have to be made or expensive modifications would be made to the existing dies. However, by employing shims 37 if the fit between channel members 20 and 22 needs to be adjusted, the profile in the die corresponding to a shim may be economically either filed or deepened which would result in a smaller or larger shim.

The resistance to undesired motion between channel members offered by the present invention permits the assembly 10 to safely carry a significant load. When an electrical fixture is secured to hanger bar assembly 10, the resultant load acting downwardly thereon tends to bow the assembly pulling the channel members apart. If the channel members, once installed, were permitted to move relative to each other, this tendency to bow would not be restricted, and the resultant sagging, would present an opportunity for the channel members to slip apart and release the outlet box. If this were to occur, the fixture could come loose from the ceiling leading to a potentially hazardous situation due to the weight of the fixture. However, by restricting relative movement between the channel members, the rigidity of the hanger bar assembly is increased, and its tendency to bow downwardly is greatly reduced. Additionally, in ceiling fan applications, the hanger bar assembly 10 experiences torque and vibrational forces as well as static vertical loadings. A hanger bar assembly's resistance to these dynamic forces is also augmented when the rigidity of the assembly is increased. In the

present invention, the requisite rigidity is obtained by preventing relative movement between channel members 20 and 22 by way of a close fit and by clamping the channel members together as described in detail below.

Referring to Figures 1 and 4, in order to prevent channel members 20 and 22 from sliding apart, the channel members are preferably urged into forced engagement when outlet box 100 is secured to hanger bar assembly 10. Outlet box 100 is secured to hanger bar assembly 10 by bracket 102 that is placed over hanger bar assembly 10 at a location where it straddles both channel members 20 and 22. Bracket 102 is generally U-shaped and has outwardly extending flanges 103 including fastener receiving apertures 41. Fasteners 104 may extend past through-holes in the back wall of outlet box 100 and threadedly engage the flange apertures 41. Box 100 and bracket 102 essentially form a clamping device whereby upon advancing fasteners 104 provides the clamping force which urges channel members 20 and 22 together to restrict all degrees of movement between the channel members. As a result of the interlocking configuration created by the rails and grooves, a substantial area of interference is created between channel members 20 and 22. The clamping force generated upon securement of outlet box 100, therefore, acts over a significant area providing hanger bar assembly 10 with the ability to resist slippage between channel members 20 and 22 even under the high loads and vibrations generated by fixtures such as ceiling fans.

The strength of the clamping force combined with the rigid profile and interlocking elements, the hanger bar assembly is able to withstand static and dynamic loads well beyond those required by the applicable codes. Accordingly, relatively heavy fixtures including ceiling fans and ornate fixtures may be safely secured to a structure such as ceiling joints.

Referring additionally to Figure 2, hanger bar assembly 10 further includes a pair of similarly formed end plates 80 attached at each end to permit the hanger bar assembly 10 to be secured to a structure. As set forth above, end plates 80 are preferably secured to the channel members 20 and 22 by fastening hardware extending through end plates 80 into securement openings 33a-c formed in channel members 20 and 30. End plates are secured to the channel members at multiple points above and below the longitudinal centerline of the

engaged channel members. Therefore, the connection resists bending moments caused by any forced acting perpendicular to the longitudinal axis. Each end plate 80 has a generally planar upper portion 81 and a leg 90 depending downwardly therefrom. The upper portion 81 of each end plate includes mounting holes 82 through which fastening hardware such as nails or screws (not shown) may be inserted into the joist thereby securing hanger assembly 10 to the joists. Screws are preferably used in order to provide the desired securement of the assembly.

Each end plate 80 preferably further includes a pair of spurs 84 that are used to temporarily hold the assembly to the joists until the fastening hardware is installed. Spurs 84 are preferably formed from a stamped out portion of the end plate itself and are shaped to form a V-shaped member as shown in Figure 1. When an installer strikes end plate 80 with a hammer, spurs 84 are driven into the joist. After the spurs of both end plates are driven into the joists, the assembly does not need to be supported by the installer. Therefore, the installer will have both hands free to install the permanent fastening hardware, which facilitates speedy permanent installation.

In order to further increase the ease of installation, downwardly depending leg 90 may include various score lines 92 along its length. Score lines 92 act as guides for locating assembly 10 with respect to the joists. It is important to properly locate the assembly since after an outlet box is secured to hanger bar assembly 10 the face of outlet box 100 must be generally flush with the front face of the ceiling covering material. The proper location of the assembly with respect to the joists is a function of outlet box depth and the ceiling covering material used. The deeper the box the higher the assembly must be secured on the joists. In addition, a plaster ceiling requires the assembly to be located lower than for a drywall ceiling. Score lines 92, therefore, are labeled 92a with the box type and ceiling material. Proper location is achieved when the score line 92 on each end plate 80 indicating the specifics of the application is aligned with the bottom of the joist. Therefore, it is preferable that the labeling 92a of the score lines be located on the side of the end plate attached to the channel member so that an installer is able to see the markings when holding the assembly up to the

joists. Additionally, score lines 92 are of such a depth that leg 90 may be easily deformed or fractured along a particular score line by the installer as required.

Although the illustrative embodiments of the present invention have been described herein with reference to the accompanied drawings, it is to be understood that the invention is not limited to those precise embodiments and that various other changes and modifications may be effected therein by one skilled in the art without departing from the scope or spirit of the invention.
